LECTURE 15

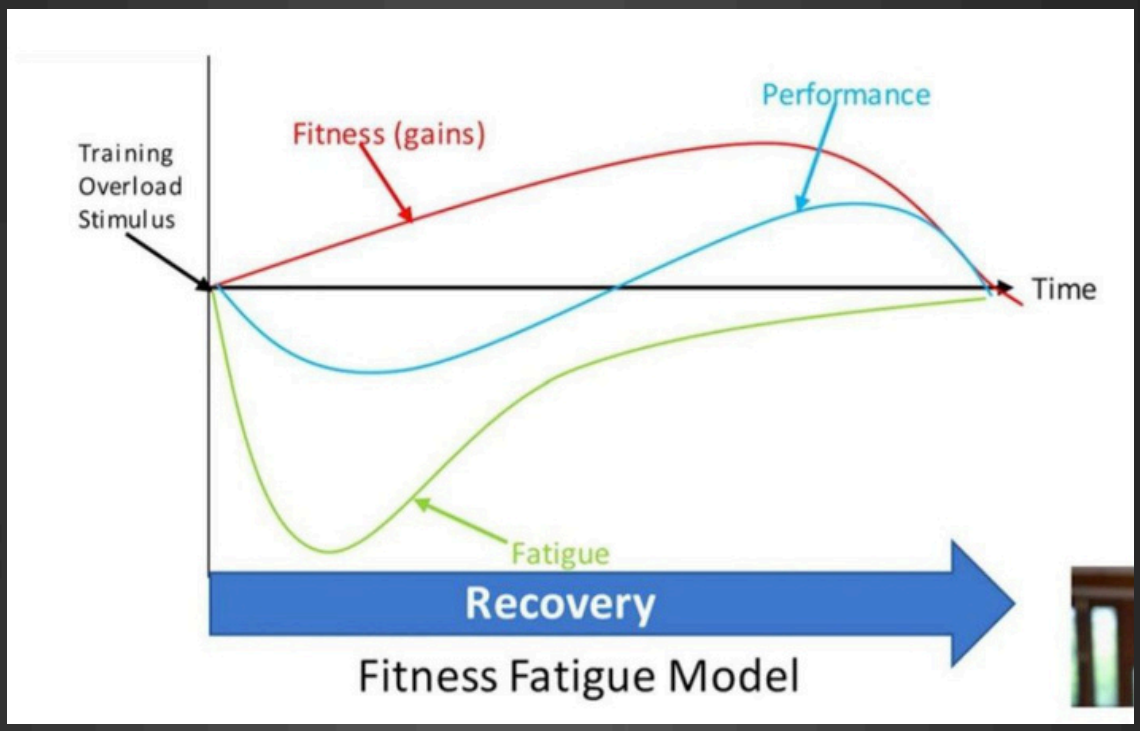
SUMMARY

MODULE 3 –LECTURE 1

Do this to grow your muscle mass

POINTS TO REMEMBER

- Always remember, there is no one rule to archieve one thing, you can reach to your goal via multiple options.
- Always open your mind and you always need to design your client's design or
- Understanding the mechanism, will truly strong your base.
- Thinking about the particle movement, while doing that movement may help you better.
- Stimulus to fatigue to recovery to adaption to hypertrophy. If you fail to manage fatigue, then the further process will be diminished, which will result in lesser hypertrophy.
- Stress bucket should be managed properly.



The key elements of the model are:

- **Training Overload Stimulus: The initial training load or overload stimulus that is applied to the body.**
- **Fitness (Gains): The positive adaptations and improvements in physical fitness that result from the training overload.**
- **Fatigue: The temporary reduction in performance capacity that occurs due to the training stress and accumulated fatigue.**

- Recovery: The process of restoring the body's physiological systems to a state where they can sustain high-level performance again.
- Performance: The overall athletic or physical capability, which is influenced by the balance between fitness gains and fatigue.

The model illustrates how the training stimulus leads to both fitness gains and fatigue over time. The goal is to manage the training and recovery process to maximize performance by optimizing the balance between fitness and fatigue.

- You always need to stimulate MPS
- Mechanical tension and angles are important in for muscles building.
- Metabolic stress occurs when you exercise and provided mechanical tension which results from lactic acid.
- Muscle damage occurs in muscles.
- Blood flow restriction (BFR):You can use this method when you are injured bcoz during injury, sometimes you have to lift lighter weights and in light weight with BFR can be an effective training as compare to only light weights training
