# LECTURE 5

SUMMARY

MODULE 1 –LECTURE 5

## TRACKING NEAT - (NON EXERCISE ACTIVITY THERMOGENESIS)

## TRACKING NEAT & MASTERING NUTRITION SKILLS

Before starting any body transformation, there are two essential components:

**One skill you must learn:** Tracking food

**One tool you must use:** Food weighing scale

Without these, accuracy becomes impossible.

## THE #1 SKILL: TRACKING YOUR FOOD INTAKE

If you want results—fat loss, muscle gain, contest prep—you must track every single bite you eat.

Tracking allows you to understand:

- how many calories you're consuming
- how much protein, carbs, and fats
- where mistakes are happening
- how consistent you are

This is the foundation of nutrition awareness.

## HOW TO TRACK PROPERLY

You must follow:

1. **Accuracy** – measure food correctly
2. **Consistency** – track daily, not occasionally
3. **Flexibility** – learn how to swap foods with equal calories
4. **Adherence** – stick to the plan
5. **Strict meal plans** – optional, but they give discipline
6. **Food avoidance** – avoid untracked snacks
7. **Food tracking apps** – if you cannot calculate manually
8. The most accurate method is **weighing everything**.

## THE #1 TOOL: FOOD WEIGHING SCALE

A weighing scale is non-negotiable.

Because:

What you think is “100g paneer” is usually never 100g.
What you think is “50g roti dough” is usually double in reality.

The scale removes guesswork.

## TRACKING NEAT & MASTERING NUTRITION SKILLS

Even when dieting, you still have flexibility:

Example:

You want to eat:

100g paneer

1 roti (50g raw weight)

You want to turn it into a paneer roll.

Good. You can do that.

But flexibility comes from understanding calories, such as:

Replacing roti with bread

Replacing paneer with soya or eggs

Adjusting food choices while keeping calories and protein constant

BUT:

If you are a serious athlete or prepping for a bodybuilding show:
→ you must maximize protein intake, even while swapping foods.

For general population:
→ Just ensure daily protein target is hit.

# WHY PROTEIN NEEDS TO BE HIGH

Protein is the building block of muscle.

**a) Protein ensures positive nitrogen balance**

This helps:

faster recovery from training stress

reduced muscle breakdown

improved strength and performance

**b) Protein builds new cells**

Cells → Tissues → Muscle (lean body mass)

Without enough protein:

tissue repair is slow

progress slows

muscle loss increases during dieting

# TOO MUCH PROTEIN VS TOO LITTLE PROTEIN

## Too Much Protein

When calories are in surplus, the body has enough energy.
Excess protein is not needed because:

carbs and fats spare protein

body does not use protein efficiently for muscle if calories are excessive

extra protein may convert into glucose via gluconeogenesis (sugar made from non-sugar sources)

## Too Little Protein

This is a bigger problem:

slow recovery

low nitrogen balance

breakdown of muscle tissue

poor training performance

lower metabolic rate over time
